Computer Assignment 2.2: String Grammar Hard C-Means

Link to assignment

1. Details of theories or methods used

String Grammar Hard C-Means (sgHCM) is an algorithm that perform a clustering of string data (text). The algorithm is very similar to k-Nearest Neighbors (KNN) algorithm as it tries to find k predefined cluster centers (centroids, prototypes), and assign the data points to a center based on the distances to the prototypes. The distinct difference of sgHCM from KNN is that the Euclidean distance used in KNN cannot be used the quantify distances between two text string. As the result, the Levenshtein distance or edit distance is utilized instead.

The Levenshtein distance is $\delta_{Lev}(w_1, w_2)$ is the smallest number of transformation needed to be taken to alter the string w_1 to string w_2 for $w_1, w_2 \in V_T^*$, which is defined as

$$\delta_{Lev}(w_1, w_2) = \begin{cases} |w_1| & \text{if } |w_2| = 0 \\ |w_2| & \text{if } |w_1| = 0 \\ \delta_{Lev}(\text{tail}(w_1), \text{tail}(w_2)) & \text{if } w_1[1] = w_2[1] \\ 1 + \min \begin{cases} \delta_{Lev}(tail(w_1), w_2) \\ \delta_{Lev}(w_1, tail(w_2)) & \text{otherwise} \end{cases} \end{cases}$$

where |x| is the length of the string x, tail of string x is the string x itself omitting the first character, and x[n] is the n^{th} character of x starting from 1. The transformations are consisted of:

- Substitution: $w_1 a w_2 \to w_1 b w_2 \ \forall a, b \in V_T \ \text{and} \ a \neq b$
- Deletion: $w_1 a w_2 \to w_1 w_2 \ \forall a \in V_T$
- Insertion: $w_1w_2 \to w_1aw_2 \ \forall a \in V_T$

The sgHCM algorithm mainly involves the iterative computation for the prototypes. For N finite strings $X = \alpha_k | k = 1, ..., N$, (user-given) number of clusters C, for $1 \leq C \leq N$, maximum number of iteration T, and terminal measure $\varepsilon_t = ||V_t - V_{t-1}||$, where ε is set to be very high at the beginning, the algorithm first randomly draw k initial string prototype $V_0 = (\alpha'_{1,0}, ..., \alpha'_{C,0})$ where $\alpha'_{i,0} \in X$ and i = 1, ..., C. Then it computes $D_{ik,t} = \delta^2_{Lev}(\alpha_k, \alpha'_{i,t-1})$ which is the distance between string α_k to the prototype.

The algorithm then populates the matrix $u_{ik,t}$ as a membership matrix of α_k in cluster i, defined as

$$u_{ik,t} = \begin{cases} 1 & \text{if } D_{ik,t} \le D_{jk,t}, \text{ for } j \ne i \\ 0 & \text{else} \end{cases}$$

And define $n_{it} = n_{it} + u_{ik,t}$. At this stage, the strings X are assigned to the nearest prototypes, that is, has the closest Levenshtein distance to it.

Next, the new prototypes $\alpha'_{i,t}$ are calculated, for cluster i=1,...,C, as $\alpha'_{i,t}=\alpha_q,$ where

$$q = \underset{1 \le j \le n_{i,t}}{\operatorname{argmin}} \left\{ c_{ij} = \sum_{s=1}^{N} \left(\frac{\delta(u_{ij,t}\alpha_t, u_{is,t}\alpha_s)}{n_{i,t}} \right) \right\}$$

meaning the string that has the minimum c_{ij} is chosen to be the new prototype for each cluster. After that the process commences again until the maximum number of iteration T is reached, or the value of terminal measure ε_t gets smaller than ε .

2. Algorithm

The algorithm is presented below. The main code is the for loop of 10-fold cross validation (10% cross validation) follows the Algorithm 1. In each fold/loop, the class sgHCM is initialized and fit for k prototypes using the training data (Algorithm 2). Then the test data is input into the class sgHCM for the prediction of the nearest prototype (Algorithm 3). The accuracy and the distance to the predicted prototype are calculated in the process.

Algorithm 1 10-fold Cross Validation

Input:

- Data: training data and test data
- k: Number of clusters
- j: Number of fold

Output:

• Average accuracy, average distance from the predicted prototype

repeat

Split data for the fold

Initialize sgHCM class, input training data for fitting (Algorithm 2)

repeat

Input the test data (Algorithm 3)

Output the nearest prototype

Calculate accuracy and distance from the predicted prototype

until Complete all test data

until Complete j fold

Algorithm 2 String Grammar Hard C-Means (fit)

Input:

- Data: A set of data points to train for prototypes
- k: The number of clusters

Output:

- Prototypes: The final cluster prototypes
- Clusters: Assignment of data points to clusters

Initialize prototypes randomly from the data points.

repeat

Assign each data point to the nearest prototype (calculate Levenshtein distance).

Update prototypes

until Prototypes no longer change significantly or max iteration reached.

Output the final prototypes and cluster assignments.

Algorithm 3 String Grammar Hard C-Means (call)

Input:

• Data: A data point \vec{x}

Output:

• The closest prototype

Compute distances from \vec{x} to the prototypes

Return the nearest prototype

3. Results and Discussions

In this section the experimental results are shown. The sgHCM algorithm is performed on the Copenhegen chromosome data for varying number of clusters k under a 10-fold cross validation.

- 3.1. **Dataset.** The dataset consists of 2200 training and 2200 test chromosome strings constructed from English uppercase and lowercase characters, and =. The data includes also the types/categories of the chromosome as number value ranged from 1 to 170 that will be used as the data's label. An example of data, e.g., 'A==A=====E==d==A==b======a' is from type 110.
- 3.2. **sgHCM Results.** We obtain the results in term of the correctness of chromosome type prediction (label), and the distance from the input test chromosome string and its assigned cluster prototype, as shown in Figures 1 (a), (b), and Table 1.
- 3.2.1. Chromosome type prediction accuracy. The accuracy is calculated as the proportion of the test sample's predicted prototype has the same type as the true prototype (0: none has the same type, 1: all have the same type). Although it seems to be increased for the larger number of k. It is found to be very low for all k. The accuracy of 0.007-0.014 reflects that only about 1.5-3 chromosome out of 220 test chromosomes in each fold are assigned to the prototype that has the same type as they are. This could suggest that a direct comparison of the type might not be suitable to use to evaluate the performance of string clustering algorithm.
- 3.2.2. **Distance from prototype**. In contrast, the average distance from the test data to their prototypes shows a decreasing trend of the average distance as the number of clusters k increased. This indicates that the test strings are more similar to the prototype as k is increased.

Overall, both measurements indicate that the performance of the algorithm increases as k increases, however at a very small margin.

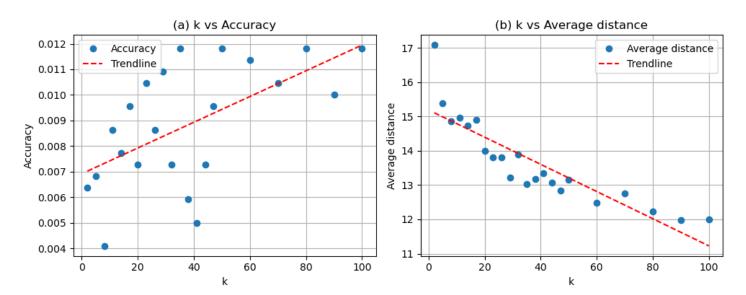

FIGURE 1. Average accuracy and distance of the test data for k = 2 - 100

k	Accuracy	Average Distance	k	Accuracy	Average Distance
2	0.0064	17.0818	35	0.0118	13.0223
5	0.0068	15.3895	38	0.0059	13.1809

32	0.0073	13.8859	100	0.0118	12.0059

Table 1. Accuracy and average distance for varied k

4. Codes

In this section the codes and output for both cases are listed. The external libraries Numpy was used mainly handle vector and matrix operations, and Matplotlib.pyplot for the graph plotting. The code follows these steps:

- 1) Read data
- 2) Run for loop, vary k
 - (a) Call cross validation function
 - (b) Initialize class sgHCM, fit the model for the prototypes
 - (c) Input test data, output accuracy, predicted labels, distance from the assigned prototype
- 3) Plot k vs accuracy, distance

The Python codes and output are listed in 4.2 and 4.3.

4.1. Comments on the implemented code. Despite it does the job, more or less, the implemented code is still far from being completed. As it can be seen that the average distance decreases as value of k is increased, the code still runs without addressing the problem that occurs when more than 2 prototypes are similar, which happens more frequent with larger k.

For the time being, when it is found that more than 2 prototypes are similar, all prototypes are redraw randomly, which is not a good strategy. One could try to merge 2 prototypes together if this happens, and/or redraw one additional prototype.

Another point is, the maximum iteration was set to only 10 iterations to allow the execution of the code for enough different k values to be completed in time. However, this is very highly sub-optimal as the terminal measure when k is large has not been reduced through the later iterations yet.

4.2. Python codes.
